

Signals, Instruments, and Systems – W3

C Programming & Memory Management in C

Any questions about the lab or
last lecture?

Outline

- Pointers
- Parameter passing
- Dynamic allocation of memory
- Debugging with gdb

Argument passing in C

- Reminder:

Arguments are always passed *by value* in C function calls! This means that **local copies** of the values of the arguments are passed to the routines!

```
#include <stdio.h>

void exchange(int a, int b) {
    int tmp = a;
    a = b;
    b = tmp;
    printf("Exchange: a = %d, b = %d\n", a, b);
}

int main() {
    int a = 5;
    int b = 7;

    exchange(a, b);

    printf("Main: a = %d, b = %d\n", a, b);

    return 0;
}
```

```
computer:~> ./exchange
computer:~> Exchange: a = 7, b = 5
computer:~> Main: a = 5, b = 7
```

What happens?

```
#include <stdio.h>

void exchange(int a, int b) {
    int tmp = a;
    a = b;
    b = tmp;
    printf("Exchange: a = %d, b = %d\n", a, b);
}

int main() {
    int a = 5;
    int b = 7;

    exchange(a,b);

    printf("Main: a = %d, b = %d\n", a, b);

    return 0;
}
```

Computer memory

Output:

```
computer:~> ./exchange
```

What happens?

```
#include <stdio.h>

void exchange(int a, int b) {
    int tmp = a;
    a = b;
    b = tmp;
    printf("Exchange: a = %d, b = %d\n", a, b);
}

int main() {
    int a = 5;
    int b = 7;

    exchange(a,b);

    printf("Main: a = %d, b = %d\n", a, b);

    return 0;
}
```

Computer memory

Output:

```
computer:~> ./exchange
```

What happens?

```
#include <stdio.h>

void exchange(int a, int b) {
    int tmp = a;
    a = b;
    b = tmp;
    printf("Exchange: a = %d, b = %d\n", a, b);
}

int main() {
    int a = 5;
    int b = 7;

    exchange(a,b);

    printf("Main: a = %d, b = %d\n", a, b);

    return 0;
}
```

Computer memory

Output:

```
computer:~> ./exchange
```

What happens?

```
#include <stdio.h>

void exchange(int a, int b) {
    int tmp = a;
    a = b;
    b = tmp;
    printf("Exchange: a = %d, b = %d\n", a, b);
}

int main() {
    int a = 5;
    int b = 7;

    exchange(a, b);

    printf("Main: a = %d, b = %d\n", a, b);

    return 0;
}
```

exchange
memory area

Computer memory

Output:

```
computer:~> ./exchange
```

What happens?

```
#include <stdio.h>

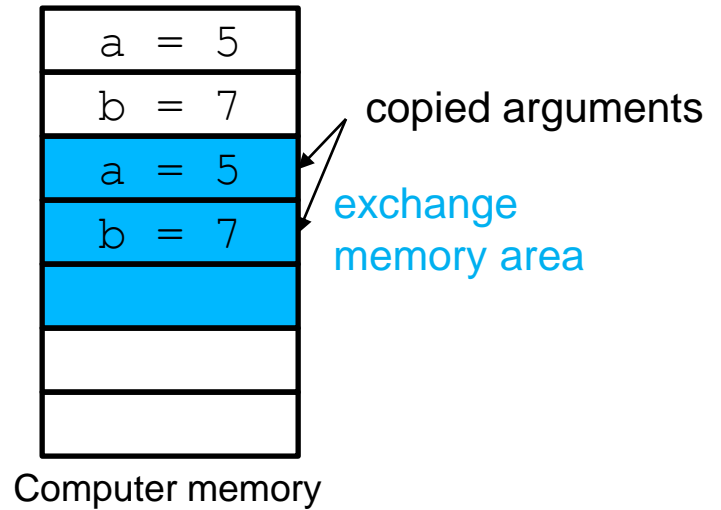

void exchange(int a, int b) {
    int tmp = a;
    a = b;
    b = tmp;
    printf("Exchange: a = %d, b = %d\n", a, b);
}

int main() {
    int a = 5;
    int b = 7;

    exchange(a, b);

    printf("Main: a = %d, b = %d\n", a, b);

    return 0;
}
```

Output:

```
computer:~> ./exchange
```

What happens?

```
#include <stdio.h>

void exchange(int a, int b) {
    int tmp = a;
    a = b;
    b = tmp;
    printf("Exchange: a = %d, b = %d\n", a, b);
}

int main() {
    int a = 5;
    int b = 7;

    exchange(a,b);

    printf("Main: a = %d, b = %d\n", a, b);

    return 0;
}
```

Output:

```
computer:~> ./exchange
```

What happens?

```
#include <stdio.h>

void exchange(int a, int b) {
    int tmp = a;
    a = b;
    b = tmp;
    printf("Exchange: a = %d, b = %d\n", a, b);
}

int main() {
    int a = 5;
    int b = 7;

    exchange(a,b);

    printf("Main: a = %d, b = %d\n", a, b);

    return 0;
}
```

Output:

```
computer:~> ./exchange
```

What happens?

```
#include <stdio.h>

void exchange(int a, int b) {
    int tmp = a;
    a = b;
    b = tmp;
    printf("Exchange: a = %d, b = %d\n", a, b);
}

int main() {
    int a = 5;
    int b = 7;

    exchange(a,b);

    printf("Main: a = %d, b = %d\n", a, b);

    return 0;
}
```

Output:

```
computer:~> ./exchange
```

What happens?

```
#include <stdio.h>

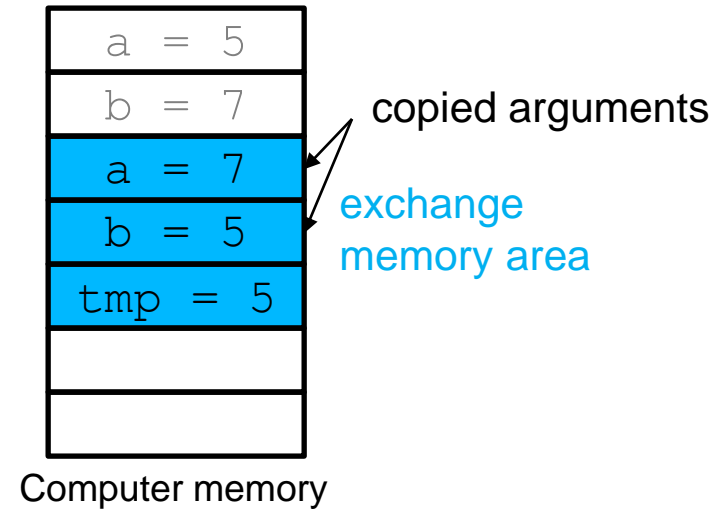

void exchange(int a, int b) {
    int tmp = a;
    a = b;
    b = tmp;
    printf("Exchange: a = %d, b = %d\n", a, b);
}

int main() {
    int a = 5;
    int b = 7;

    exchange(a,b);

    printf("Main: a = %d, b = %d\n", a, b);

    return 0;
}
```

Output:

```
computer:~> ./exchange
computer:~> Exchange: a = 7, b = 5
```

What happens?

```
#include <stdio.h>

void exchange(int a, int b) {
    int tmp = a;
    a = b;
    b = tmp;
    printf("Exchange: a = %d, b = %d\n", a, b);
}

int main() {
    int a = 5;
    int b = 7;

    exchange(a,b);

    printf("Main: a = %d, b = %d\n", a, b);

    return 0;
}
```

Computer memory

Output:

```
computer:~> ./exchange
computer:~> Exchange: a = 7, b = 5
```

What happens?

```
#include <stdio.h>

void exchange(int a, int b) {
    int tmp = a;
    a = b;
    b = tmp;
    printf("Exchange: a = %d, b = %d\n", a, b);
}

int main() {
    int a = 5;
    int b = 7;

    exchange(a,b);

    printf("Main: a = %d, b = %d\n", a, b);

    return 0;
}
```

Computer memory

Output:

```
computer:~> ./exchange
computer:~> Exchange: a = 7, b = 5
computer:~> Main: a = 5, b = 7
```

Pointers

Anti-confusion tips

- Which one to choose ? `&var`, `var`, or `*var` ?

1. ‘`&var`’ can never come before an ‘`=`’

2. Look for the type:

```
float i;
```

```
float *p;
```

```
p = &i;
```

```
*p = 2.4;
```

– `p` is a pointer to float, `*p` is a float.

Argument passing in C

- Arguments are always passed *by value* in C function calls! This means that **local copies** of the values of the arguments are passed to the routines!

```
#include <stdio.h>

void exchange(int a, int b) {
    int tmp = a;
    a = b;
    b = tmp;
    printf("Exchange: a = %d, b = %d\n", a, b);
}

int main() {
    int a = 5;
    int b = 7;

    exchange(a, b);

    printf("Main: a = %d, b = %d\n", a, b);

    return 0;
}
```

```
computer:~> ./exchange
computer:~> Exchange: a = 7, b = 5
computer:~> Main: a = 5, b = 7
```

How to solve the problem?

- By using **pointers**, i.e. variables that contain the address of another variable!

```
#include <stdio.h>

void exchange(int* pa, int* pb) {
    int tmp = *pa;
    *pa = *pb;
    *pb = tmp;
    printf("Exchange: a = %d, b = %d\n", *pa, *pb);
}

int main() {
    int a = 5;
    int b = 7;

    exchange(&a, &b);

    printf("Main: a = %d, b = %d\n", a, b);

    return 0;
}
```

Output:

```
computer:~> ./exchange
computer:~> Exchange: a = 7, b = 5
computer:~> Main: a = 7, b = 5
```

int* pa and **int* pb** are pointers!

What happens now?

```
#include <stdio.h>

void exchange(int *pa, int *pb) {
    int tmp = *pa;
    *pa = *pb;
    *pb = tmp;
    printf("Exchange: a = %d, b = %d\n", *pa, *pb);
}

int main() {
    int a = 5;
    int b = 7;

    exchange(&a, &b);

    printf("Main: a = %d, b = %d\n", a, b);

    return 0;
}
```

Addresses

Output:

```
computer:~> ./exchange
```

What happens now?

```
#include <stdio.h>

void exchange(int *pa, int *pb) {
    int tmp = *pa;
    *pa = *pb;
    *pb = tmp;
    printf("Exchange: a = %d, b = %d\n", *pa, *pb);
}

int main() {
    int a = 5;
    int b = 7;

    exchange(&a, &b);

    printf("Main: a = %d, b = %d\n", a, b);

    return 0;
}
```

computer:~> Exchange: a = 7, b = 5
computer:~> Main: a = 7, b = 5
```

Arrays

- Arrays and pointers are closely related.

```
float v[3];
v[0] = 1.3;
v[1] = 4.5;
v[2] = 5.2;
```

- `v` points to the first element of the array

	Type	Address	Value
<code>v</code>	<code>float*</code>	4	8
<code>v[1]</code>	<code>float</code>	<code>v+1=12</code>	4.5

- `v` is the same as `&(v[0])`
- `v[0]` is the same as `*(v+0)`
- `v[1]` is the same as `*(v+1)`

Passing an array to a function

```
#include <stdio.h>

#define SIZE 3

void g(int* array_p, int const size) {
    int i;

    for (i = 0; i < size; ++i) {
        array_p[i] = 2 * (i+1);
    }
}

int main(void) {
    int i;
    int array[SIZE] = {0, 0, 0} ;

    g(array, SIZE);

    for (i = 0; i < SIZE; ++i) {
        printf("%d:%d ", i, array[i]);
    }

    return 0;
}
```

- The two variables **array_p** and **array** are not the same (**array_p** is a pointer to the first element of **array**)!
- For the purpose of modifying the array from the function g(), **array_p** acts the same as **array**

- Here is the output of the program:

```
computer:~> gcc -o array2fun array2fun.c
computer:~> ./array2fun
computer:~> 0:2 1:4 2:6
```

Strings

- There is no string type in C. Instead, we use arrays of `char`, i.e. the type `char*`.

```
char str[] = "hello";
```

	Type	Address	Value
<code>str</code>	<code>char*</code>		2
<code>str[4]</code>	<code>char</code>	<code>str+4</code>	<code>'o'</code>
<code>str[2]</code>	<code>char</code>	<code>str+2</code>	<code>'l'</code>

Computer memory

- You can use the `printf` to print out chains of characters. It will read up to the character `'\0'`.

```
printf("%s", str);    → computer:~> hello
printf("%s", str+3); → computer:~> lo
```

Memory: a more realistic approach

- In a real computer, memory is organized into blocks of 8 bits, called **bytes**.
- On most modern computers, each byte has its own address.
- Memory is **limited**, not only in terms of the number of RAM modules that are installed, but also in terms of the number of addresses available.
- Furthermore, a program is not allowed to use (read and/or write) all bytes: some are reserved by the operating system. If you try to access them (using a pointer), your program will crash (segmentation fault or bus error).

8-bit computer memory

```
int *p = 1;
*p = 0;
```

→ segmentation fault (trying to write at address 1)

The size of the data types

- Each data type requires a certain number of bytes to be stored in memory, and this size can change as a function of the operating system (Windows, Linux, etc.) and the architecture of the system.
- The function `sizeof (type)` returns the size of the data type (in bytes).

```
printf ("%d", sizeof (char));      /* prints 1 */  
printf ("%d", sizeof (short));    /* prints 2 */  
printf ("%d", sizeof (int));      /* prints 4 */  
printf ("%d", sizeof (long));     /* prints 4 */  
printf ("%d", sizeof (float));    /* prints 4 */  
printf ("%d", sizeof (double));   /* prints 8 */
```

The size of pointers

- **Reminder:** a pointer is a **variable** that contains **the address of another variable**.
- Therefore, the size of any pointer is **constant**, regardless of the data type that it points to (since it contains only the address of the variable, which does not depend on its type, obviously).

```
printf("%d", sizeof(char*)); /* prints 4 */  
printf("%d", sizeof(short*)); /* prints 4 */  
printf("%d", sizeof(int*)); /* prints 4 */  
printf("%d", sizeof(long*)); /* prints 4 */  
printf("%d", sizeof(float*)); /* prints 4 */  
printf("%d", sizeof(double*)); /* prints 4 */
```

On a 32-bit computer

The size of pointers

- **Reminder:** a pointer is a **variable** that contains **the address of another variable**.
- Therefore, the size of any pointer is **constant**, regardless of the data type that it points to (since it contains only the address of the variable, which does not depend on its type, obviously).

```
printf ("%d", sizeof (char*));      /* prints 8 */  
printf ("%d", sizeof (short*));    /* prints 8 */  
printf ("%d", sizeof (int*));      /* prints 8 */  
printf ("%d", sizeof (long*));     /* prints 8 */  
printf ("%d", sizeof (float*));    /* prints 8 */  
printf ("%d", sizeof (double*));   /* prints 8 */
```

On a 64-bit computer

```
#include <stdio.h>

int main() {
    int i = 10;
    int** p1;
    int* p2;

    p1 = &p2;
    *p1 = &i;
    *p2 /= 2;

    printf("i = %d\n", i);

    return 0;
}
```

Output:

computer:~> ./pointers

```
#include <stdio.h>
```

```
int main() {
```

```
    int i = 10;  
    int** p1;  
    int* p2;
```

```
    p1 = &p2;  
    *p1 = &i;  
    *p2 /= 2;
```

```
    printf("i = %d\n", i);
```

```
    return 0;
```

```
}
```

Output:

```
computer:~> ./pointers
```

```
#include <stdio.h>
```

```
int main() {  
    int i = 10;  
    int** p1;  
    int* p2;
```

```
p1 = &p2;
```

```
*p1 = &i;
```

```
*p2 /= 2;
```

```
printf("i = %d\n", i);
```

```
return 0;
```

```
}
```

Output:

```
computer:~> ./pointers
```

```
#include <stdio.h>

int main() {
    int i = 10;
    int** p1;
    int* p2;

    p1 = &p2;
    *p1 = &i;
    *p2 /= 2;

    printf("i = %d\n", i);

    return 0;
}
```

Output:

computer:~> ./pointers

```
#include <stdio.h>
```

```
int main() {  
    int i = 10;  
    int** p1;  
    int* p2;  
  
    p1 = &p2;  
    *p1 = &i;  
    *p2 /= 2;  
  
    printf("i = %d\n", i);  
  
    return 0;  
}
```

Output:

```
computer:~> ./pointers
```

```
#include <stdio.h>
```

```
int main() {  
    int i = 10;  
    int** p1;  
    int* p2;  
  
    p1 = &p2;  
    *p1 = &i;  
    *p2 /= 2;
```

```
printf("i = %d\n", i);
```

```
return 0;
```

```
}
```

Output:

```
computer:~> ./pointers  
computer:~> i = 5
```

Dynamic allocation of memory

- MATLAB automatically grows matrices as you continue to add more elements
- These data structures are **dynamical** because they grow automatically in memory as you add data to them.
- In C, you **cannot** do that without managing memory yourself.
- In this code sample, for instance, the array `signal` can contain 50 integers and you cannot make it grow further.
- In many cases, you do not know at **compile time** the size of your data structure. In such cases, you need to **allocate memory dynamically!**

This value has to be a constant!

```
int signal[50];  
signal[0] = 0;  
signal[1] = 4;  
signal[2] = 5;  
signal[3] = 4;  
signal[4] = 3;  
...
```

Dynamic allocation of memory

- To allocate a certain amount of memory, you can use the function `malloc(size)`, where *size* is the number of bytes of memory requested (which does not have to be constant).
- `malloc` returns a pointer to the first byte of memory which has been allocated.
- As a result, the static array declaration `int signal[50]` becomes, in its dynamic version:

```
int* signal = malloc(50 * sizeof(int));  
signal[0] = 0;  
signal[1] = 4;  
signal[2] = 5;  
signal[3] = 4;  
signal[4] = 3;  
...
```

This value does not have to be a constant!

Freeing the memory

- If you allocated some memory dynamically, the compiler will **not** take care of freeing the allocated block of memory when you no longer need it.
- Use the function `free(void *ptr)` to make the block available to be allocated again.
- If you perform a `malloc` without its `free` counterpart, you will create a memory leak.
- Therefore, write a `free` for each `malloc` you write.
- After you free memory, you can no longer access it.

```
int* signal = malloc(50 * sizeof(int));  
  
// ...  
  
free(signal);
```

```
#include <stdlib.h>

#define MAX_SIZE 1000000

int main() {
    int i;
    int *v; // a vector

    // create a vector of size i
    for (i = 1; i < MAX_SIZE; ++i) {
        v = malloc(i*sizeof(int));
        // do something with vector v
    }

    return 0;
}
```

- Each iteration of the loop, an increasingly larger chunk of memory is allocated with **malloc**
- These chunks are never freed, and the program allocates a total of 2,000 GB of memory before terminating!

```
#include <stdlib.h>

#define MAX_SIZE 1000000

int main() {
    int i;
    int *v; // a vector

    // create a vector of size i
    for (i = 1; i < MAX_SIZE; ++i) {
        v = malloc(i*sizeof(int));
        // do something with vector v
        free (v) ; // free memory
    }

    return 0;
}
```

- Each iteration of the loop, an increasingly larger chunk of memory is allocated with **malloc**
- These chunks are never freed, and the program allocates a total of 2,000 GB of memory before terminating!
- Calling **free** inside the loop means that we never allocate more than 4 MB at a time

Beyond this lecture

- What you learned today are the *basics* of memory management, i.e., **what you need to know as a C programmer.**
- There are further subtleties, which we **do not expect you to understand in depth**, but it is worth knowing that they exist:
 - the ordering of individually addressable units (words, bytes, or even bits) within a longer data word (endianness) might differ from platform to platform
 - memory is actually divided into two parts: (i) the **stack**, on which variables that are declared at **compile time** are stored in order of **decreasing address**; (ii) the **heap**, on which variables that are **dynamically allocated** are stored.
 - there are further types of memory, which you cannot access in C without resorting to assembler instructions: (i) the **registers**, which are located inside the processor, are extremely fast, but very limited (a few hundreds of bytes); (ii) the **cache**, which is a fast, but small memory (a few megabytes), and is used by the processor to perform “caching” (i.e., pre-fetching and storing chunks of data that are likely to be used or re-used soon).
- Most of these details are **platform-dependent** (and therefore mostly handled by the compiler)

Debugging with gdb

```
#include <stdio.h>
```

```
int main() {  
    int i = 10;  
    int** p1;  
    int* p2;
```

```
    p1 = &p2;
```

```
    *p1 = &i;
```

```
    *p2 /= 2;
```

```
    return 0;
```

```
}
```

← What is the value of **i**?

← What about now?

Debugging

- Debuggers allow you to step through and examine the effects of your code as it executes
- Many IDEs have a visual debugger built in, but in this class we will use `gdb`, which operates from the command line
- `gdb` has tons of features, but we only need to know a few for it to be an extremely powerful tool

```
$ gcc -g -o pointers pointers.c
```

```
$ gdb ./pointers
```

```
(gdb) start
```

Basic commands

- Start your program by typing `start` at the `gdb` prompt
- Your program will execute until it reaches a "breakpoint". A breakpoint is automatically inserted at the first line of your main function.
- Breakpoints are added with "`break filename.c:<line>`"
- Execution can be resumed with "`continue`"

Debugging example

(gdb)

Debugging example

```
(gdb) start
```

```
(gdb) start
Temporary breakpoint 1, main () at pointers.c:4
4          int i = 10;
(gdb)
```

```
(gdb) start
Temporary breakpoint 1, main () at pointers.c:4
4          int i = 10;
(gdb) break pointers.c:10
```

Debugging example

```
(gdb) start
```

```
Temporary breakpoint 1, main () at pointers.c:4
```

```
4          int i = 10;
```

```
(gdb) break pointers.c:10
```

```
Breakpoint 2 at 0x4011b8: file pointers.c, line 10.
```

```
(gdb)
```

Debugging example

```
(gdb) start
```

```
Temporary breakpoint 1, main () at pointers.c:4
```

```
4          int i = 10;
```

```
(gdb) break pointers.c:10
```

```
Breakpoint 2 at 0x4011b8: file pointers.c, line 10.
```

```
(gdb) continue
```

```
(gdb) start
Temporary breakpoint 1, main () at pointers.c:4
4         int i = 10;
(gdb) break pointers.c:10
Breakpoint 2 at 0x4011b8: file pointers.c, line 10.
(gdb) continue
Continuing.
Breakpoint 2, main () at pointers.c:10
10  *(&p2[1]-1) /= 2;
(gdb)
```

Inspecting variables

- To inspect the values of different variables, use the "print" command

```
Breakpoint 2, main () at pointers.c:10
10 *(&p2[1]-1) /= 2;
(gdb)
```

Inspecting variables

- To inspect the values of different variables, use the "print" command

```
Breakpoint 2, main () at pointers.c:10
10 *(&p2[1]-1) /= 2;
(gdb) print &i
```

Inspecting variables

- To inspect the values of different variables, use the "print" command

```
Breakpoint 2, main () at pointers.c:10
10 *(&p2[1]-1) /= 2;
(gdb) print &i
$1 = (int *) 0x28abf8
(gdb)
```

Inspecting variables

- To inspect the values of different variables, use the "print" command

```
Breakpoint 2, main () at pointers.c:10
10 *(&p2[1]-1) /= 2;
(gdb) print &i
$1 = (int *) 0x28abf8
(gdb) print &p2[1]-1
```

Inspecting variables

- To inspect the values of different variables, use the "print" command

```
Breakpoint 2, main () at pointers.c:10
```

```
10 *(&p2[1]-1) /= 2;
```

```
(gdb) print &i
```

```
$1 = (int *) 0x28abf8
```

```
(gdb) print &p2[1]-1
```

```
$2 = (int *) 0x28abf8
```

Step by step navigation

- Setting a breakpoint on every line of a function would be very tedious!
- Use the `step` and `next` commands to navigate through your code one line at a time
- `step` will enter function calls
- `next` will skip them

```
int main() {  
    myfunction(a);  
    printf("a = %d\n", a);  
  
    return 0;  
}
```

```
void myfunction(int a) {  
    // perform calculations  
}
```

Step by step navigation

- Setting a breakpoint on every line of a function would be very tedious!
- Use the `step` and `next` commands to navigate through your code one line at a time
- `step` will enter function calls
- `next` will skip them

```
int main() {  
    myfunction(a);  
    printf("a = %d\n", a);  
  
    return 0;  
}
```

```
void myfunction(int a) {  
    // perform calculations  
}
```

    // perform calculations  
}
```

Conclusion

Take-home messages

- A pointer is a variable that contains the address of another variable.
- An array is not a pointer, but acts like one in most cases! Arrays simply address a sequence of values.
- Memory can be either **statically** (at compile time) or **dynamically** (at run time) allocated:
 - **Static allocation** does not require manual deallocation.
 - **Dynamic allocation** requires manual deallocation (using `free`).
- Recall that computer memory has multiple layers of complexity, even though **we do not expect you to know them in details**.
- Debugging with `printf` is still okay, but a debugger like `gdb` can be more useful in many situations
